A: Create an executable, .EXE, using psexec that runs your "naked" test, then add it to the users startup as an application that never gets closed. This approach has worked for me in the past, and should work in this case as well. 0 Flares Twitter 0 Facebook 0 Filament.io 0 Flares x We like the way that @sciart\_tidus does his homework before he does any artwork. Check out his work here: Or look at his Twitter for more updates. @sciart\_tidus @Nemesor\_M asked him a question and he answered it pretty neatly: Wow... I can't believe this drew up on the spot! Thanks for the awesome question and patience as I go through the process. Reading a current

directory before Docker builds Overview  
The main reason I want to read and parse a current directory before a Docker build is so I can update the image before it's even built. A lot of repos are going the other way, uploading images to the Serverless Application Repository (a cloud hosted service) while they're being built in Docker. I've done a bit of reverse engineering of this relationship to create my own tool, called FakeRepo, so that when I upload builds to the Repo, they're rejected if they're older than those in the repository. The problem was that I didn't want to implement it this way, because it's too brittle. So I created the bulk-builder which lets you read a directory, and not just one file, and detect whether the files are newer or not. I wanted to make sure that my builds were working properly so I could hack the tool to do what I want, but it was also a challenge because I didn't want to make changes to a public, hosted service

---

just for me. I've found that I can access my fake Repo much more easily when I'm logged in as root with a service account. Using the `get_image_builder` method in `serverless.prod.js` let me log in with a service account and pull
